

Part 1 – Hardware vs Software

***Explain Hardware**

● Hardware refers to the physical parts of a computer that can be seen and touched, such as the keyboard, mouse, monitor, CPU, printer, and speakers. These parts help the computer receive input, process information, store data, and display output. For example, the keyboard is used for typing, while the monitor shows the results on the screen. Without hardware, a computer cannot function because there would be no physical equipment to perform tasks.

***Explain Software**

● Software is a collection of programs and instructions that tell the computer what to do. Unlike hardware, software cannot be touched because it exists in digital form. Examples of software include operating systems like Windows, web browsers, games, and applications such as Microsoft Word. Software helps users perform tasks like writing documents, browsing the internet, and watching videos. Without software, hardware would not know how to operate.

***How Do Hardware and Software interact ?**

● Hardware and software work together to make a computer function properly. Software provides instructions, while hardware carries out the tasks. For example, when a user types on the keyboard, the hardware sends information to the software, which processes it and displays the text on the monitor. The operating system acts as a bridge between hardware and software, helping them communicate efficiently. Both are equally important because hardware cannot work without software, and software cannot run without hardware.
